Update on . . . Survivorship Care Plans
Susan Weiss Behrend, RN, MSN, AOCN® • Associate Editor

The focus of this column is to present topics of interest from a variety of journals to Oncology Nursing Forum readers. The topic of this issue is the transition from patient to survivor and the clinical use of survivorship care plans.

Bridging the Transition From Patient With Cancer to Survivor

The purpose of this pilot study was to test the feasibility of a telephone counseling program for cancer survivors. The Cancer Survivor Telephone Education and Personal Support (C-STEPS) program was developed to address psychosocial and health behavior outcomes among cancer survivors. According to Garrett et al. (2013), this was the first telephone counseling intervention to simultaneously address psychosocial and health behavior in this patient population.

In this study, participants (N = 66) were recruited from two Colorado hospitals. C-STEPS was evaluated using a single-arm, intervention-only research design, and participants served as their own controls. Eligibility criteria included having stage I, II, or III disease; having the last treatment or follow-up assessment; 21 selected stress and coping, 13 selected healthy behaviors. All participants, including 46 participants who completed at least one module and the follow-up assessment, 21 selected both modules, 13 selected stress and coping and 12 selected healthy behaviors.

Overall, participants were highly satisfied with the program, with a mean overall satisfaction rating of 9 on a scale of 1–10. Participant’s rated the usefulness of telephone counseling at a mean of 8.8. Cancer-specific distress was assessed using the Impact of Event Scale (IES). On the IES intrusion subscale, 67% of participants reported moderate distress or higher at baseline. Among all participants, a significant decrease in mean cancer-specific intrusive thoughts was observed, going from 10.2 to 6.5 (p < 0.001). On the IES avoidance subscale, 59% of participants reported moderate levels of distress at baseline, as indicated by cancer-specific avoidance behavior. Participants who chose the Healthy Options module (n = 33) showed a statistically significant increase in daily consumption of fruits and vegetables, going from 3.8 to 4.6 daily servings (p = 0.02). For all participants (n = 46), an increase in physical activity was noted, going from 166.8 to 242 minutes per week (p = 0.006).

This study successfully tested the feasibility of focused telephone counseling to facilitate the adaptation from patient with cancer to survivor. The findings indicated that C-STEPS provides a viable telephone counseling program with the capacity to address cancer-related distress and promote healthy lifestyle initiatives for survivors. Cancer programs in the United States seeking accreditation by the American College of Surgeons will soon require mandatory distress screening and services for patients with cancer. With that in mind, psychosocial telephone counseling, such as C-STEPS, may become integral models for cancer survivorship programs.

Survivorship Care Plans and Support From Providers

This study aimed to describe barriers to the clinical implementation of survivorship care plans (SCPs), strategies to support the use of SCPs by healthcare providers, and issues related to the relevance of SCPs. An SCP is a personalized, portable document used to facilitate continuous comprehensive medical care following cancer treatment and is used by patients and primary care providers. Although primary care providers and survivors have embraced the concept of SCPs, Salz et al. (2014) recognized that SCPs have not been widely used because of significant barriers. Therefore, the purpose of this study was to survey National Cancer Institute-designated Community Cancer Centers
