Factors Affecting Quality of Life for Korean American Cancer Survivors: An Integrative Review

Hyojin Yoon, PhD, RN, Linda Chatters, PhD, Tsui-Sui Annie Kao, PhD, FNP-BC, Denise Saint-Arnault, PhD, RN, FAAN, and Laurel Northouse, PhD, RN

The size of the Asian American population living in the United States is projected to increase by 132% and will comprise 9% of the total U.S. population by 2050 (U.S. Census Bureau, 2011). Compared to Caucasians, African Americans, and Hispanics, Asian Americans have distinctive profiles for leading causes of death. Cancer is the leading cause of death for Asian Americans (Centers for Disease Control and Prevention, 2013). Specific information on Asian American subgroups indicates that Korean Americans have the highest cancer mortality rates (Kwong, Chen, Snipes, Bal, & Wright, 2005) and the lowest breast and colorectal cancer screening rates (Lee, Ju, Vang, & Lundquist, 2010; Lee, Lundquist, Ju, Luo, & Townsend, 2011; Maxwell, Crespi, Antonio, & Lu, 2010). Korean American men (55 per 100,000) and women (28 per 100,000) have the highest incidence of stomach cancer compared to other Asian subgroups, which is five times higher than rates for non-Hispanic Caucasian men and seven times higher than rates for non-Hispanic Caucasian women (McCracken et al., 2007). Korean American women have the highest incidence and mortality rates for liver cancer compared to other Asian American subgroups, and Korean American men have the second highest incidence and mortality rates for liver and colorectal cancer (McCracken et al., 2007). Given the high incidence of cancer among Korean Americans and the dramatic increase in the percentage of Korean Americans (33%) living in the United States since 2000 (U.S. Census Bureau, 2012), oncology professionals likely will be caring for...
