Meaning-Making and Psychological Adjustment to Cancer: Development of an Intervention and Pilot Results

Virginia Lee, N, PhD, S. Robin Cohen, PhD, Linda Edgar, N, PhD, Andrea M. Laizner, N, PhD, and Anita J. Gagnon, N, PhD

Purpose/Objectives: To develop an intervention that uniquely addresses the existential impact of cancer through meaning-making coping strategies and to explore the intervention’s impact on psychological adjustment.

Design: Descriptive, qualitative approach to develop the intervention; one-group pre- and post-test design to pilot test the intervention.

Setting: Patients’ homes or ambulatory oncology clinics affiliated with a university health center in eastern Canada.

Sample: 18 participants who were newly diagnosed in the past three months (n = 14), had completed treatment (n = 1), or were facing recurrence (n = 3) of breast (n = 10) or colorectal (n = 8) cancer.

Methods: Data were collected during interviews using a prototype intervention for trauma patients, and content was analyzed on an ongoing basis to fit the needs of the cancer population. Pretest and post-test questionnaires were administered to determine the intervention’s effect.

Main Research Variables: Meaning-making intervention (MMI), patients’ background variables, disease- or treatment-related symptoms, and psychological adjustment.

Findings: The MMI for patients with cancer consisted of as many as four two-hour, individualized sessions and involved the acknowledgment of losses and life threat, the examination of critical past challenges, and plans to stay committed to life goals. At post-test, participants significantly improved in self-esteem and reported a greater sense of security in facing the uncertainty of cancer.

Conclusions: Findings suggest that meaning-making coping can be facilitated and lead to positive psychological outcomes following a cancer diagnosis.

Implications for Nursing: The MMI offers a potentially effective method to overcome and possibly grow from the repercussions of cancer.

Although only a third of patients with cancer experience severe psychological distress (Derogatis et al., 1983; Farber, Weinerman, & Kuypers, 1984; Stefanek, Derogatis, & Shaw, 1987; Zabora, Brintzenhofeszoc, Curbow, Hooker, & Piantadosi, 2001), guidelines for the delivery of optimal comprehensive cancer care are based on the premise that every patient at every stage of the disease experiences some degree of psychological discomfort (Council of the Canadian Strategy for Cancer Control, 2004; Holland, 1999, 2000). Existential distress, defined as the state of an individual confronting his or her own mortality arising from feelings of powerlessness, disappointment, futility, meaninglessness, remorse, death anxiety, and disruption with his or her engagement with and purpose in life (Kissane, 2000), appears to be a ubiquitous part of the cancer experience. Meaning-making coping increasingly is recognized as a possible mechanism by which existential concerns can be addressed (Coward, 1998, 2003; Folkman & Greer, 2000; Lee, Cohen, Edgar, Laizner, & Gagnon, 2004; Mullen, Smith, & Hill, 1993; Taylor, 2000).
